

## Building a smart cardiac patch

'Bionic' cardiac patch could one day monitor, respond to cardiac problems

*Date:* June 27, 2016

*Source:* Harvard University

*Summary:* Researchers have created nanoscale electronic scaffolds that can be seeded with cardiac cells to produce a 'bionic' cardiac patch. Once implanted, the bionic patch could act similarly to a pacemaker -- delivering electrical shocks to correct arrhythmia, but the possibilities don't end there, say researchers.

### FULL STORY

---

Unlike traditional pacemakers, the new bionic patch -- because its electronic components are integrated throughout the tissue -- can detect arrhythmia far sooner, and operate at far lower voltages, say researchers.

Scientists and doctors in recent decades have made vast leaps in the treatment of cardiac problems -- particularly with the development in recent years of so-called "cardiac patches," swaths of engineered heart tissue that can replace heart muscle damaged during a heart attack.

Thanks to the work of Charles Lieber and others, the next leap may be in sight.

The Mark Hyman, Jr. Professor of Chemistry and Chair of the Department of Chemistry and Chemical Biology, Lieber, postdoctoral fellow Xiaochuan Dai and other co-authors of a study that describes the construction of nanoscale electronic scaffolds that can be seeded with cardiac cells to produce a "bionic" cardiac patch. The study is described in a June 27 paper published in *Nature Nanotechnology*.

"I think one of the biggest impacts would ultimately be in the area that involves replaced of damaged cardiac tissue with pre-formed tissue patches," Lieber said. "Rather than simply implanting an engineered patch built on a passive scaffold, our works suggests it will be possible to surgically implant an innervated patch that would now be able to monitor and subtly adjust its performance."

Once implanted, Lieber said, the bionic patch could act similarly to a pacemaker -- delivering electrical shocks to correct arrhythmia, but the possibilities don't end there.

"In this study, we've shown we can change the frequency and direction of signal propagation," he continued. "We believe it could be very important for controlling arrhythmia and other cardiac conditions."

Unlike traditional pacemakers, Lieber said, the bionic patch -- because its electronic components are integrated throughout the tissue -- can detect arrhythmia far sooner, and operate at far lower voltages.

"Even before a person started to go into large-scale arrhythmia that frequently causes irreversible damage or other heart problems, this could detect the early-stage instabilities and intervene sooner," he said. "It can also continuously monitor the feedback from the tissue and actively respond."

"And a normal pacemaker, because it's on the surface, has to use relatively high voltages," Lieber added.

The patch might also find use, Lieber said, as a tool to monitor the responses under cardiac drugs, or to help pharmaceutical companies to screen the effectiveness of drugs under development.

Likewise, the bionic cardiac patch can also be a unique platform, he further mentioned, to study the tissue behavior evolving during some developmental processes, such as aging, ischemia or differentiation of stem cells into mature cardiac cells.

Although the bionic cardiac patch has not yet been implanted in animals, "we are interested in identifying collaborators already investigating cardiac patch implantation to treat myocardial infarction in a rodent model," he said. "I don't think it would be difficult to build this into a simpler, easily implantable system."

In the long term, Lieber believes, the development of nanoscale tissue scaffolds represents a new paradigm for integrating biology with electronics in a virtually seamless way.

Using the injectable electronics technology he pioneered last year, Lieber even suggested that similar cardiac patches might one day simply be delivered by injection.

"It may actually be that, in the future, this won't be done with a surgical patch," he said. "We could simply do a co-injection of cells with the mesh, and it assembles itself inside the body, so it's less invasive."
